A plot of this data is below: What I'm trying to do is get a method of evaluating this. My first thought was to count the local maxima. The obvious problem here is that if the data is not evenly sampled, then it will count, say, 3 maxima as 2 maxima, but I'd like to evaluate the maxima not on a monotonically increasing function, but on a evenly spaced function. I can do this in python fairly easily, but before I start writing a loop that is a pain to write and debug, I thought I'd ask the math stack exchange to see if there is a nice, clean, etc, way of doing it. A: It sounds like you just want to compare all of the "valleys" to one another and to the top value, so you can use a K-means cluster analysis of the series, and then compare these (potentially) overlapping clusters to one another. A simple way to do this is to use the maxima and minima in an Excel Pivot Table, and group values, then count the maxima/minima within each group: Then you just want to compare each of these clusters to the next one, then the next one, and so on until the number of clusters is equal to the number of maxima/minima: If you have a large number of clusters you 3ef4e8ef8d
